Lecture 1: Hidden Markov Model

Zheng-Hua Tan

Department of Electronic Systems Aalborg University, Denmark zt@es.aau.dk

Readings in VGIS, Zheng-Hua Tan

1

Hidden Markov model (HMM)

- A statistical model in which the system being modeled is assumed to be a Markov process with unobserved state.
- In a regular Markov model, the state is directly visible to the observer, and therefore the state transition probabilities are the only parameters.
- In an HMM, the state is not directly visible, but output dependent on the state is visible.
 - Each state has a probability distribution over the possible output tokens. Therefore the sequence of tokens generated by an HMM gives some information about the sequence of states.
 - The adjective 'hidden' refers to the state sequence through which the model passes, not to the parameters of the model.

A three-state Markov model

The weather on day t is characterised by a single one of the three states

Example:A three-state model of the weather

the weather

State 1: precipitation (rain, snow, hail, etc.) State 2: cloudy State 3: sunny

 The above stochastic process is considered an observable Markov model since the output process is a set of states at each instant of time, where each state corresponds to an observable event.

Readings in VGIS, Zheng-Hua Tan

5

Basic calculations

Example: What is the probability that the weather for eight consecutive days is "sun-sun-rain-rain-sun-cloudy-sun"?

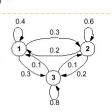

Solution:

$$\begin{split} P(\overline{O}|Model) &= P[3]P[3|3]P[3|3]P[1|3]P[1|1]P[3|1]P[2|3]P[3|2] \\ &= \pi_3 a_{33} a_{31} a_{11} a_{13} a_{32} a_{23} \end{split}$$

 $= 1.536 \times 10^{-4}$

Example:A three-state model of the weather

State 1: precipitation (rain, snow, hail, etc.) State 2: cloudy State 3: sunny

(After Joseph Picone)

Readings in VGIS, Zheng-Hua Tan

Log-Domain Mathematics

Multiplying many numbers together brings in the risk of underflow errors.

A solution: Transform everything into the log domain:

$$\begin{array}{c|cccc} \underline{linear\ domain} & \underline{log\ domain} \\ \hline x^y & \log(x^y) = e^{\log(y)} \cdot \log(x) & e^y \cdot x \\ x \cdot y & \log(x \cdot y) = \log(x) + \log(y) & x + y \\ x + y & \log Add(x, y) = x + \log(1 + e^{y - x}) \end{array}$$

logAdd(x,y) computes sum of x and y when both x and y are already in log domain.

$$\log(x+y) = \log\left(x + \left[\frac{y}{x} \cdot x\right]\right)$$

$$\log\left(x \left[1 + \frac{y}{x}\right]\right)$$

$$\log(x) + \log\left(1 + \frac{y}{x}\right)$$

$$\log(x) + \log\left(1 + e^{\log(y) - \log(x)}\right)$$
(Hosom, 2006)

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

7

Log-Domain Mathematics

log-domain mathematics avoids underflow, allows (expensive) multiplications to be transformed to (cheap) additions.

Typically used in HMMs where there are a large number of Multiplications, O(F) where F is the number of frames.

If *F* is moderately large (e.g. 5 seconds of speech = 500 frames), even large probabilities (e.g. 0.9) yield small results:

$$0.9^{500} = 1.3 \times 10^{-23}$$

 $0.65^{500} = 2.8 \times 10^{-94}$

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

The Markov chain

- Consider a system described at any time t as being in one of a set of N states indexed by {1,2,...,N}
- Denote the actual state at time t as q_t
- So, the first-order Markov chain is

$$P[q_t = j | q_{t-1} = i, q_{t-2} = k,...] = P[q_t = j | q_{t-1} = i]$$

 We consider those processes in which the right-side of the equation above is independent of time, leading to statetransition probabilities

$$a_{ii} = P[q_t = j \mid q_{t-1} = i], \quad 1 \le i, j \le N$$

with constraints:

 $a_{ij} \geq 0 \qquad \forall j,$

 $\sum_{j=1}^{N} a_{ij} = 1 \quad \forall i$

Example:A three-state model of the weather

State 1: precipitation (rain, snow, hail, etc. State 2: cloudy State 3: sunny

0.3 0.1 0.2 2 0.1 0.2 3

Part II: Hidden Markov model

- Markov chain
- Hidden Markov model
- Basic calculations
 - □ How to evaluate an HMM the forward algorithm
 - □ How to decode an HMM the Viterbi algorithm
 - How to estimate HMM parameters Baum-Welch Algorithm
- Continuous and discrete HMMs

AL BORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

What is an HMM

- Hidden Markov Model:
 - more than 1 event associated with each state.
 - all events have some probability of emitting at each state.
 - given a sequence of outputs, we can't determine exactly the state sequence.
 - We can compute the probabilities of different state sequences given an output sequence.
- Doubly stochastic (probabilities of both emitting events and transitioning between states); exact state sequence is "hidden."

Readings in VGIS, Zheng-Hua Tan

13

Elements of a discrete HMM

- N: the number of states
 - \Box states, $s = \{s_1, s_2, ..., s_N\}$
 - □ state at time t, $q_t \in s$
- M: the number of observation symbols
 - \Box observation symbols, $v = \{v_1, v_2, ..., v_M\}$
 - □ observation at time t, $o_t \in v$
- $A = \{a_{ii}\}$: state transition probability distribution
 - $a_{ij} = P(q_{t+1} = s_i | q_t = s_i), 1 \le i,j \le N$
- B = {b_i(k)}: observation probability distribution in state j
 - □ $b_i(k) = P(O_t = v_k | q_t = s_i), 1 \le j \le N, 1 \le k \le M$
- $\pi = {\pi_i}$: initial state distribution
- For convenience, we use the notation: $\lambda = (A, B, \pi)$

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

Elements of an HMM

- · HMM is specified by:
- states q^i
- ⊙ k a t ⊙
- transition probabilities a_{ij}

k 0.9 0.1 0.0 0.0 k 0.9 0.1 0.0 0.0 a 0.0 0.9 0.1 0.0 t 0.0 0.0 0.9 0.1

- $p(q_n^j \middle| q_{n-1}^i) \equiv a_{ij}$
- emission distributions $b_i(x)$ $p(x|q^i) \equiv b_i(x)^{p(x|q)}$

+ (initial state probabilities $p(q_1^i) \equiv \pi_i$)

From Dan Ellis, 2004.

Readings in VGIS, Zheng-Hua Tan

15

What is an HMM

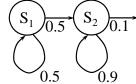

an HMM still *generates* observations, each state is still discrete,

(Hosom, 2006)

- observations can still come from a finite set (discrete HMMs).
- the number of items in the set of events does not have to be the same as the number of states.
- when in state *S*,

there's $p(e_1)$ of generating event 1, there's $p(e_2)$ of generating event 2, etc.

 $p_{SI}(black) = 0.3$ $p_{SI}(white) = 0.7$

 $p_{S2}(black) = 0.6$ $p_{S2}(white) = 0.4$

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

What is an HMM

- must know all possible states in advance
- must know possible state connections in advance
- cannot recognize things outside of model
- must have some estimate of state emission probabilities and state transition probabilities
- make several assumptions (usually so math is easier)
- if we can find best state sequence through an HMM for a given observation, we can compare multiple HMMs for recognition.

Readings in VGIS, Zheng-Hua Tan

17

HMM Topologies

Ergodic (fully-connected) $\begin{array}{c}
0.6 \\
0.3 \\
\pi_1 = 0.4 \\
\pi_2 = 0.2 \\
\pi_3 = 0.4
\end{array}$ Bakis (left-to-right) $\begin{array}{c}
\pi_1 = 1.0 \\
\pi_2 = 0.0 \\
\pi_2 = 0.0 \\
\pi_3 = 0.0 \\
\pi_4 = 0.0
\end{array}$ $\begin{array}{c}
0.6 \\
0.7 \\
0.7 \\
0.5
\end{array}$

- •Topology defined by the state transition matrix (If an element of this matrix is zero, there is no transition between those two states).
- •The topology must be specified in advance by the system designer

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

Part III: Three HMM calculations

- Markov chain
- Hidden Markov model

 - □ How to evaluate an HMM the forward algorithm
 - □ How to decode an HMM the Viterbi algorithm
 - How to estimate HMM parameters Baum-Welch Algorithm
- Continuous and discrete HMMs

Readings in VGIS, Zheng-Hua Tan

19

Three basic HMM problems

- Scoring: Given an observation sequence O = {o₁,o₂,...,o_T} and a model λ = {A, B,π}, how to compute P(O | λ), the probability of the observation sequence?
 → The Forward-Backward Algorithm
- 2. **Matching:** Given an observation sequence $O = \{o_1, o_2, ..., o_T\}$ and the model λ , how to choose a state sequence $\mathbf{q} = \{q_1, q_2, ..., q_T\}$ which is optimum in some sense? \rightarrow The Viterbi Algorithm
- **Training:** How to adjust the model parameters $\lambda = \{A, B, \pi\}$ to maximize $P(\mathbf{O}|\lambda)$? \rightarrow The Baum-Welch Reestimation Procedures

AALBORG UNIVERSITY

 $Readings\ in\ VGIS,\ Zheng-Hua\ Tan$

Problem 1: Scoring

- Given $O = \{o_1, o_2, ..., o_T\}$ and $\lambda = \{A, B, \pi\}$, how to compute $P(O \mid \lambda)$, the probability of the observation sequence? (probability evaluation)
 - \Box Consider all possible state sequences (N^T) of length T:

$$P(O \mid \lambda) = \sum_{all \, \mathbf{q}} P(O \mid q, \lambda) P(q \mid \lambda)$$

$$= \sum_{q_1, q_2, \dots, q_T} \pi_{q_1} b_{q_1}(O_1) a_{q_1 q_2} b_{q_2}(O_2) \dots a_{q_{T-1} q_T} b_{q_T}(O_T)$$

- Calculation required $\approx N^T \cdot 2T$
 - □ For N =5,T = 100, $2 \cdot 100 \cdot 5^{100} \approx 10^{72}$ computations!

Readings in VGIS, Zheng-Hua Tan

21

The forward algorithm

- Consider the forward variable $\alpha_{t}(i)$ defined as $\alpha_t(i) = P(o_1 o_2 ... o_t, q_t = i \mid \lambda)$
- i.e., the probability of the partial observation sequence until time t and state i at time t, given the model λ
- We can solve for $\alpha_t(i)$ inductively as follows:
 - 1. Initialisation

$$\alpha_1(i) = \pi_i b_i(o_1), \qquad 1 \le i \le N$$

2. Induction
$$\alpha_{t+1}(j) = \left[\sum_{i=1}^N \alpha_t(i) a_{ij}\right] b_j(o_{t+1}), \qquad 1 \leq t \leq T-1$$

$$1 \leq j \leq N$$

$$P(O \mid \lambda) = \sum_{i=1}^N \alpha_T(i)$$

$$P(O \mid \lambda) = \sum_{i=1}^{N} \alpha_{T}(i)$$

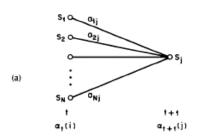

Calculation≈T N². For N=5,T=100, 2500, instead of 10⁷²

Readings in VGIS, Zheng-Hua Tan

Illustration of forward algorithm

From (Rabiner, 1989)

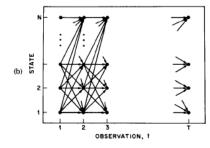

Fig. 4. (a) Illustration of the sequence of operations required for the computation of the forward variable $\alpha_{t+1}(j)$. (b) Implementation of the computation of $\alpha_t(i)$ in terms of a lattice of observations t, and states i.

AALBORG UNIVERSIT

Readings in VGIS, Zheng-Hua Tan

23

The backward algorithm

- Similarly, consider the backward variable $\beta_t(i)$ defined as $\beta_t(i) = P(o_{t+1}o_{t+2}...o_T \mid q_t = i, \lambda)$
- i.e., the probability of the partial observation sequence from time t +1 to the end, given state i at time t and model λ
- We can solve for $\beta_t(i)$ inductively as follows:
 - 1. Initialisation

$$\beta_T(i) = 1, \qquad 1 \le i \le N$$

2. Induction

2. Induction
$$\beta_t(i) = \sum_{j=1}^N a_{ij} b_j(o_{t+1}) \beta_{t+1}(j), \qquad t = 1$$
3. Termination
$$P(O \mid \lambda) = \sum_{i=1}^N \pi_i b_i(o_1) \beta_1(i)$$

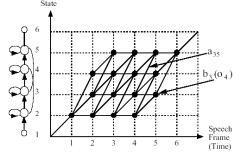

$$P(O | \lambda) = \sum_{i=1}^{N} \pi_i b_i(o_1) \beta_1(i)$$

Again, calculation≈N2.T.

 $Readings\ in\ VGIS,\ Zheng-Hua\ Ta_{Fig.\ 5.}\ \ Illustration\ of\ the\ sequence\ of\ operations\ req for\ the\ computation\ of\ the\ backward\ variable\ \mathcal{B}_{i}(t).$

Problem 2: Matching

• Given $O = \{o_1, o_2, ..., o_T\}$, how to choose a state sequence $q = \{q_1, q_2, ..., q_T\}$ which is optimum in some sense? ("Optimal" state sequence)

Trellis diagram for an Isolated Word Recognition task. From (Young et al. 1997, p. 10)

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

25

Finding optimal state sequence

- One optimality criterion is to choose the states q_i that are individually most likely at each time t

observation sequence O, and the model
$$\lambda$$

$$\gamma_t(i) = P(q_t = i \mid O, \lambda) = \frac{P(O, q_t = i \mid \lambda)}{P(O \mid \lambda)} = \frac{P(O, q_t = i \mid \lambda)}{\sum\limits_{i=1}^{N} P(O, q_t = i \mid \lambda)}$$
 Since $P(O, q_t = i \mid \lambda) = q_t(i) \beta_t(i)$

Since $P(O, q_t = i \mid \lambda) = \alpha_t(i)\beta_t(i)$

We have
$$\gamma_t(i) = \frac{\alpha_t(i)\beta_t(i)}{\sum\limits_{i=1}^{N} \alpha_t(i)\beta_t(i)}$$

 \Box The individually most likely state q_t^* at time t is

$$q_{t}^{*} = \arg\max_{1 \leq i \leq N} [\gamma_{t}(i)]$$

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

Finding optimal state sequence (cont'd)

- The individual optimality criterion has the problem that the optimum state sequence may not obey state transition constraints →
 The "optimal" state sequence may not even be a valid sequence (a_{ii}=0 for some i and j)
- Another optimality criterion is is to find the single best state sequence (path), i.e., to maximize
 P(q, O|λ) →

The Viterbi algorithm – a method based on dynamic programming

Readings in VGIS, Zheng-Hua Tan

27

The Viterbi algorithm

■ To find the best path $\mathbf{q} = \{q_1, q_2, ..., q_T\}$, for given $\mathbf{O} = \{o_1, o_2, ..., o_T\}$, we define the best score (highest probability) along a single path, at time t,

$$\delta_{t}(i) = \max_{q_{1}, q_{2}, \dots, q_{t-1}} P(q_{1}q_{2} \dots q_{t-1}, q_{t} = i, o_{1}o_{2} \dots o_{t} \mid \lambda)$$

which accounts for the first *t* observations and ends in state *i*.

Then

$$\delta_{t+1}(j) = [\max_{i} \delta_{t}(i)a_{ij}].b_{j}(o_{t+1})$$

AL BORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

The Viterbi algorithm (cont'd)

- 1. Initialisation $\delta_1(i) = \pi_i b_i(o_1), \quad 1 \le i \le N$ $\psi_1(i) = 0$
- 2. Recursion

$$\begin{split} & \delta_t(j) = \max_{1 \leq i \leq N} [\delta_{t-1}(i)a_{ij}]b_j(o_t), \qquad 2 \leq t \leq T \quad 1 \leq j \leq N \\ & \psi_t(j) = \arg\max_{1 \leq i \leq N} [\delta_{t-1}(i)a_{ij}], \qquad 2 \leq t \leq T \quad 1 \leq j \leq N \end{split}$$

3. Termination

$$P^* = \max_{1 \le i \le N} [\delta_T(i)]$$

$$q_T^* = \arg \max_{1 \le i \le N} [\delta_T(i)]$$

4. Path (state sequence) backtracking

$$q_t^* = \psi_{t+1}(q_{t+1}^*), \qquad t = T-1, T-2, ..., 1$$

AALBORG UNIVERSITY

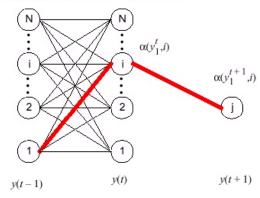

Readings in VGIS, Zheng-Hua Tan

29

The Viterbi algorithm (cont'd)

From Joseph Picone

The *Viterbi algorithm* can also be used to find the best state sequence. Note that the principal difference is that we model the overall sequence probability by the probability of the single best path:

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

The power of recursive equation

Computing factorials *n*!

Method 1. simply caculate n! for each n

Method 2. use n! = n(n-1)!

if F(n) = n! then

F(n) = nF(n-1) for $n \ge 1$

(Recursive Equation)

Readings in VGIS, Zheng-Hua Tan

31

Problem 3: Training

- How to tune the model parameters $\lambda = \{A, B, \pi\}$ to maximize $P(\mathbf{O}|\lambda)$? a learning problem
 - No efficient algorithm for global optimisation
 - Effective iterative algorithm for local optimisation: the Baum-Welch re-estimation
- Baum-Welch
 - = forward-backward algorithm (Baum, 1972)
 - is a special case of EM (expectation-maximization) algorithm
 - \Box computes probabilities using current model λ ;
 - refines λ to $\overline{\lambda}$ such that $P(\mathbf{O}|\lambda)$ is locally maximised
 - \Box uses α and β from forward-backward algorithm

Readings in VGIS, Zheng-Hua Tan

Baum-Welch re-estimation

Define $\xi_t(i, j)$, the probability of being in state i at time t, and state j at time t+1, given λ and O, i.e.

$$\begin{aligned} \xi_{t}(i,j) &= P(q_{t} = i, q_{t+1} = j \mid \mathbf{O}, \lambda) \\ &= \frac{P(q_{t} = i, q_{t+1} = j, \mathbf{O} \mid \lambda)}{P(\mathbf{O} \mid \lambda)} \\ &= \frac{\alpha_{t}(i)a_{ij}b_{j}(\mathbf{o}_{t+1})\beta_{t+1}(j)}{P(\mathbf{O} \mid \lambda)} \\ &= \frac{\alpha_{t}(i)a_{ij}b_{j}(\mathbf{o}_{t+1})\beta_{t+1}(j)}{\sum\limits_{i=1}^{N}\sum\limits_{j=1}^{N}\alpha_{t}(i)a_{ij}b_{j}(\mathbf{o}_{t+1})\beta_{t+1}(j)} \end{aligned}$$

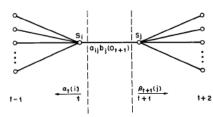

Fig. 6. Illustration of the sequence of operations required for the computation of the joint event that the system is in state S_i at time t and state S_j at time t + 1.

Readings in VGIS, Zheng-Hua Tan

33

Baum-Welch Re-estimation (cont'd)

■ Recall that $\gamma_t(i)$ is defined as the probability of being in state i at time t, given the entire observation sequence and the model, so

$$\gamma_{t}(i) = P(q_{t} = i \mid O, \lambda) = \sum_{j=1}^{N} P(q_{t} = i, q_{t+1} = j \mid O, \lambda) = \sum_{j=1}^{N} \xi_{t}(i, j)$$

• Sum $\gamma_t(i)$ and $\xi_t(i,j)$ over t, we have

$$\sum_{t=1}^{T-1} \gamma_t(i) = \text{expected number of transitions from state } i \text{ in } \mathbf{O}$$

$$(\sum_{t=1}^{T} \gamma_t(i))$$
 = the expected number of times that state *i* is visitied.)

 $\sum_{t=1}^{T-1} \xi_t(i,j) = \text{expected number of transitions from state } i \text{ to state } j \text{ in } \mathbf{O}$

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

Baum-Welch re-estimation formulas

 $\overline{\pi}_i$ = expected frequency (number of times) in state i

at time
$$(t = 1) = \gamma_1(i)$$

 $\overline{a}_{ij} = \frac{\text{expected number of transitions from state } i \text{ to state } j$

expected number of transitions from state i

$$= \frac{\sum_{t=1}^{T-1} \xi_t(i,j)}{\sum_{t=1}^{T-1} \gamma_t(i)}$$

 $\overline{b}_{i}(k) = \frac{\text{expected number of times in state } j \text{ and observing symbol } v_{k}$

expected number of times in state j

$$= \frac{\sum_{t=1}^{T} \gamma_{t}(j)}{\sum_{t=1}^{T} \gamma_{t}(j)} = \frac{\sum_{t=1}^{T} P(O, q_{t} = i \mid \lambda) \cdot \delta(o_{t}, v_{k})}{\sum_{t=1}^{T} P(O, q_{t} = i \mid \lambda)}$$

$$\delta(o_{t}, v_{k}) = \begin{cases} 1 & o_{t} = v_{k} \\ 0 & \text{otherwise} \end{cases}$$

$$\delta(o_t, v_k) = \begin{cases} 1 & o_t = v_k \\ 0 & \text{otherwise} \end{cases}$$

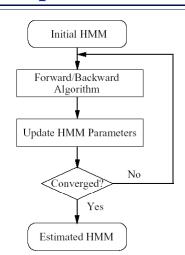

35

Parameter re-estimation process

- $\lambda = \{A, B\}$ Initialize
- Compute α , β , and ξ
- Estimate $\overline{\lambda} = {\overline{A}, \overline{B}}$ from ξ
- Replace λ with $\bar{\lambda}$
- If not converged go to 2

It can be shown that

$$P(O \mid \overline{\lambda}) > P(O \mid \lambda) \text{ unless } \overline{\lambda} = \lambda$$

Readings in VGIS, Zheng-Hua Tan

Basic operations in HMMs

For an observation sequence $O = O_1...O_7$, the three basic HMM operations are:

Problem	Algorithm	Complexity
Evaluation:	Forward-Backward	O(TN ²)
Calculating $P(q_t=S_i \mid O_1O_2O_t)$		
Inference:	Viterbi Decoding	O(TN ²)
Computing $Q^* = argmax_Q P(Q O)$, ,
Learning:	Baum-Welch (EM)	O(TN ²)
Computing $\lambda^* = \arg\max_{\lambda} P(O \lambda)$		= (:)

T = # timesteps, N = # states

37

Part VI: Continuous and discrete HMMS

- Markov chain
- Hidden Markov model
- Basic calculations
 - How to evaluate an HMM the forward algorithm
 - □ How to decode an HMM the Viterbi algorithm
 - How to estimate HMM parameters Baum-Welch Algorithm
- Continuous and discrete HMMs

AAI BORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

Vector quantization

- Vector Quantization (VQ) is a method of automatically partitioning a feature space into different clusters based on training data.
- Given a test point (vector) from the feature space, we can determine the cluster that this point should be associated with.
- A "codebook" lists central locations of each cluster, and gives each cluster a name (usually a numerical index).
- This can be used for data reduction (mapping a large number of feature points to a much smaller number of clusters), or for probability estimation.
- Requires data to train on, a distance measure, and test data.

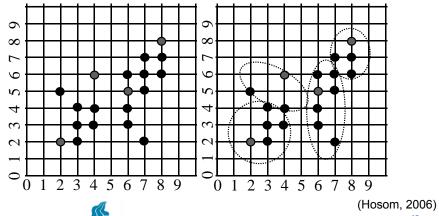

Readings in VGIS, Zheng-Hua Tan

39

Vector quantization – an example

Given the following data points, create codebook of 4 clusters, with initial code word values at (2,2), (4,6), (6,5), and (8,8)

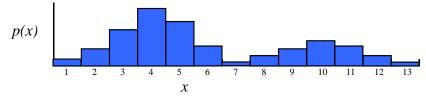

AALBORG UNIVERSITY

 $Readings\ in\ VGIS,\ Zheng-Hua\ Tan$

Vector quantization

- Features \Leftrightarrow observations, probability of feature = $b_i(\mathbf{o}_t)$
- However, quantization error can arise when modeling a continuous signal (feature space) with discrete units (clusters)

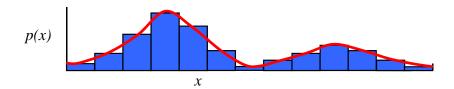

- What happens to p(x) if feature space moves back and forth between bins 3 and 4? What about between bins 5 and 6?
- In addition, initialization can influence the location and histogram counts of the final clusters... want more robustness (Hosom, 2006)

Readings in VGIS, Zheng-Hua Tan

Continuous probability distribution

- What we want is a smooth, robust estimate of p(x) (and $b_i(\mathbf{o}_i)$)!!
- How about this:

- Now, small movement along x axis has smooth, gradual effect on p(x).
- Still a question about initialization...

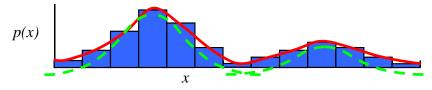

(Hosom, 2006)

AALBORG UNI

Readings in VGIS, Zheng-Hua Tan

Continuous probability distribution

- One way of creating such a smooth model is to use a mixture of Gaussian probability density functions (p.d.f.s).
- The detail of the model is related to the number of Gaussian components
- This Gaussian Mixture Model (GMM) is characterized by
 - (a) the number of components,
 - (b) the mean and standard deviation of each component,
 - (c) the weight (height) of each component

• One remaining question: how to compute probabilities from p.d.f. at one point (a single *x* value) (Hosom, 2006)

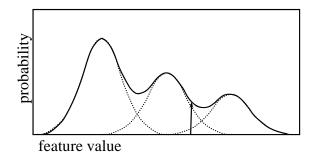

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

43

Gaussian mixture models

- Typical HMMs for speech are continuous-density HMMs
- Use Gaussian Mixture Models (GMMs) to estimate probability of "emitting" each observation given the speech category (state).

• Features \Leftrightarrow observations, probability of feature = $b_i(\mathbf{o}_t)$

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

(Hosom, 2006)

Continuous density HMMs

- Replaces the discrete observation probabilities, $b_j(k)$, by a continuous PDF (probability density function) $b_j(x)$
- The PDF b_j(x) is often represented as a mixture of Gaussians:

 c_{jk} is the mixture weight, $c_{jk} \ge 0$, and $\sum_{k=1}^{M} c_{jk} = 1$

$$b_{j}(\mathbf{x}) = \sum_{k=1}^{M} c_{jk} N[\mathbf{x}, \mu_{jk}, \sum_{jk}]$$
 $1 \le j \le N$

N is the normal density

The mean and covariance matrix associated with state j and mixture k

AALBORG UNIVERSITY

Readings in VGIS, Zheng-Hua Tan

45

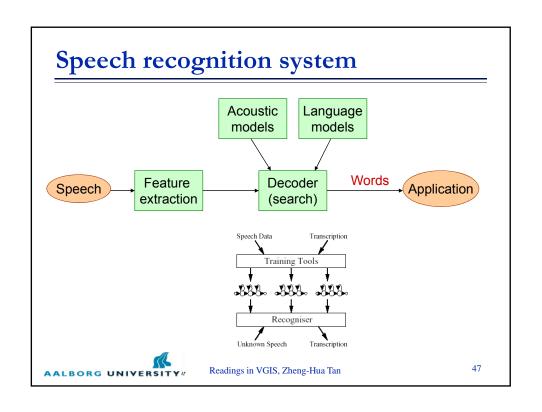

Continuous vs discrete HMMs

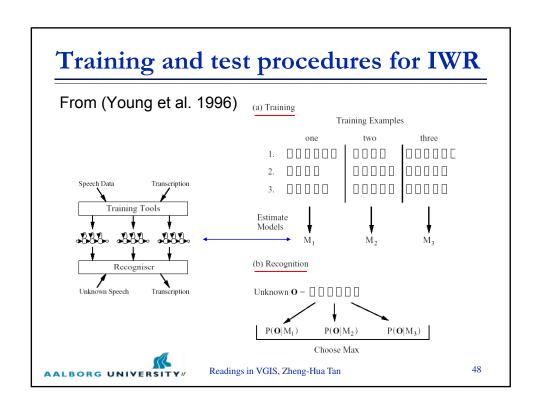

Comparing continuous (GMM) and discrete (VQ) HMMs:

- Continuous HMMs:
 - o assume independence of features for diagonal matrix
 - require large number of components to represent arbitrary function
 - large number of parameters = slow, can't always train well
 - o small number of components may not represent speech well
- Discrete HMMs:
 - quantization errors at boundaries
 - o relies on how well VQ partitions the space
 - sometimes problems estimating probabilities when unusual input vector not seen in training

AALBORG UNIVERSITY

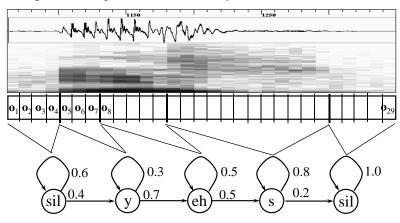

Readings in VGIS, Zheng-Hua Tan

HMMs for speech

• Example of using HMM for word "yes" on an utterance:

Summary

- Markov chain
- Hidden Markov model
- Basic calculations
 - □ How to evaluate an HMM the forward algorithm
 - □ How to decode an HMM the Viterbi algorithm
 - How to estimate HMM parameters Baum-Welch Algorithm
- Continuous and discrete HMMs

AALBORG UNIVERSITY
